

Tutorial 6

Sol 1) Minimum spanning tree is a subset of the edges of a connected edge-weighted undirected graph that connects all the vertices together without any cycles & with the minimum possible total edge weight.

Applications -

- ① Consider n stations are to be linked using a communication network and laying of communication link between any two stations involves a cost.
- ② The ideal solution would be to extract a subgraph termed as minimum cost spanning tree.
- ③ Suppose you want to construct highways or railroads spanning several cities, then we can use the concept of minimum spanning trees.
- ④ Designing LAN
- ⑤ Laying pipelines connecting offshore drilling sites, refineries & consumer markets.
- ⑥ Suppose you meant to apply a set of houses with-
 - Electric Power
 - Water
 - Telephone lines
 - Sewage lines

Sol 2) - Time complexity of Prim's algorithm: $O(|E| \log |V|)$

Space complexity of Prim's algo: $O(|V|)$

→ Time complexity of Kruskal's algo: $O(|V| \log |E|)$

→ Space complexity of Kruskal's algo: $O(|V|)$.

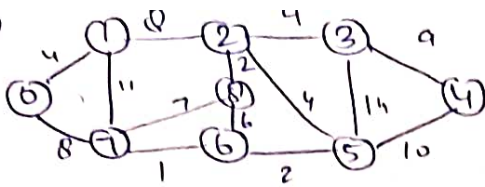

→ T.comp. of Dijkstra's algo: $O(V^2)$

→ S.comp. of Dijkstra's algo: $O(V^2)$

→ T.comp. of Bellman Ford's algo - $O(VE)$

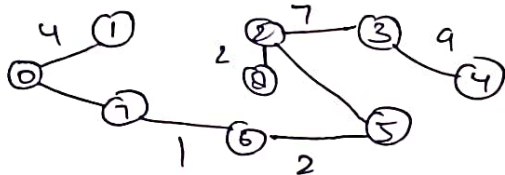

→ Space complexity of Bellman Ford's algo - $O(E)$

Sol 3)

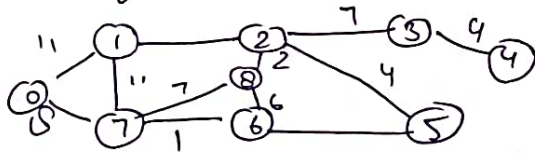

Kruskal's algorithm:

D	V	W		D	V	W	
6	7	1	✓	4	3	9	✓
5	6	2	✓	4	5	10	x
2	8	2	✓	1	7	11	x
6	1	4	✓	3	3	14	x
2	5	4	✓				
6	8	6	x				
2	3	7	✓				
7	8	7	x				
6	7	8	✓				
1	2	8	x				

$$\text{weight} = 1 + 2 + 2 + 4 + 4 + 7 + 8 + 9 = 37$$

Prim's algorithm -

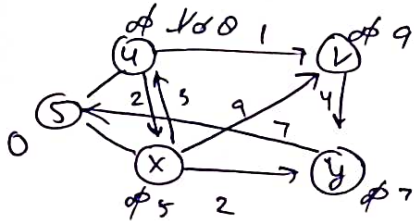

$$\text{weight} = 4 + 4 + 9 + 10 + 2 + 7 + 1 = 37$$

Sol 4 i) The shortest path may change. The reason is there may be different number of edges in different paths from 's' to 't'. For eg, let shortest path be of weight 15 and has 5 edges.

Let there be another path with 2 edges and total weight 25. The weight of the shortest path is increased by 5% and becomes 15.75. Weight of the other path is increased by 2% and becomes 25.5. So, the shortest path changes to the other path with weight as 25.5.

(ii) If we multiply all edges weight by 60, the shortest path doesn't change. The reason is simple, weights of all paths from 's' to 't', get multiplied by same amount. The number of edges on a path doesn't matter. It was like changing units of weights.

Sol 5 - Dijkstra Algorithm

node	shortest dist from source node
u	2
v	9
x	5
y	7

→ Bellman ford algorithm -

1st → s(0) u(10) v(∞) x(5) y(∞)

2nd → s(0) u(2) v(11) x(5) y(∞)

3rd → s(0) u(2) v(9) x(5) y(7)

4th → s(0) u(2) v(9) x(5) y(7)

graph doesn't have -ve cycle.

final graph -
